# Dynamo for Spilt Slab
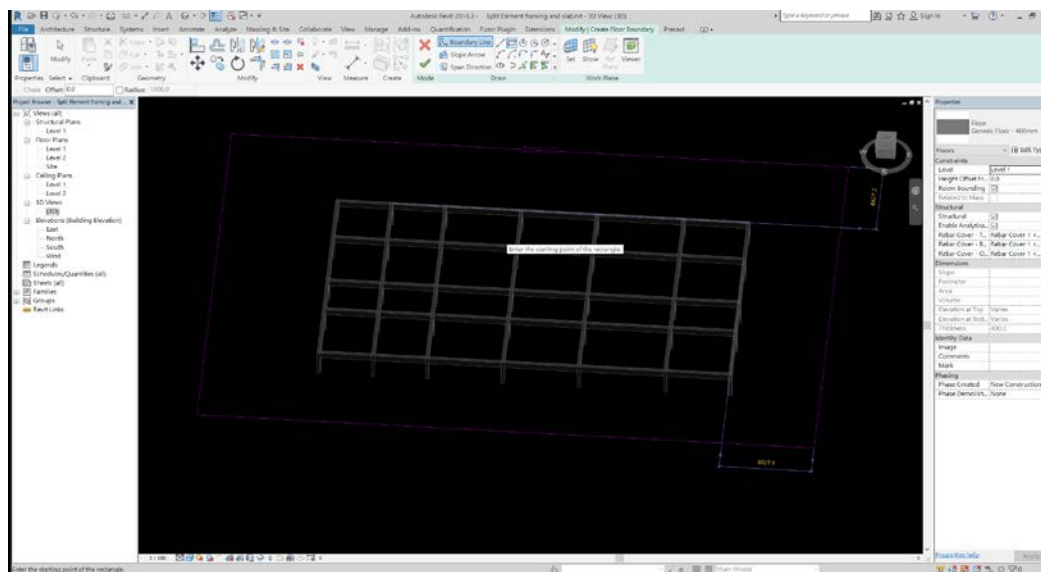

Finish the framing plan first, and please don't choose the wrong type element (Categories naming should be Structure Framing, Structure Column…..)

If you can use the Gridline to form it, that is the best way to visualize the framing plan in Revit.

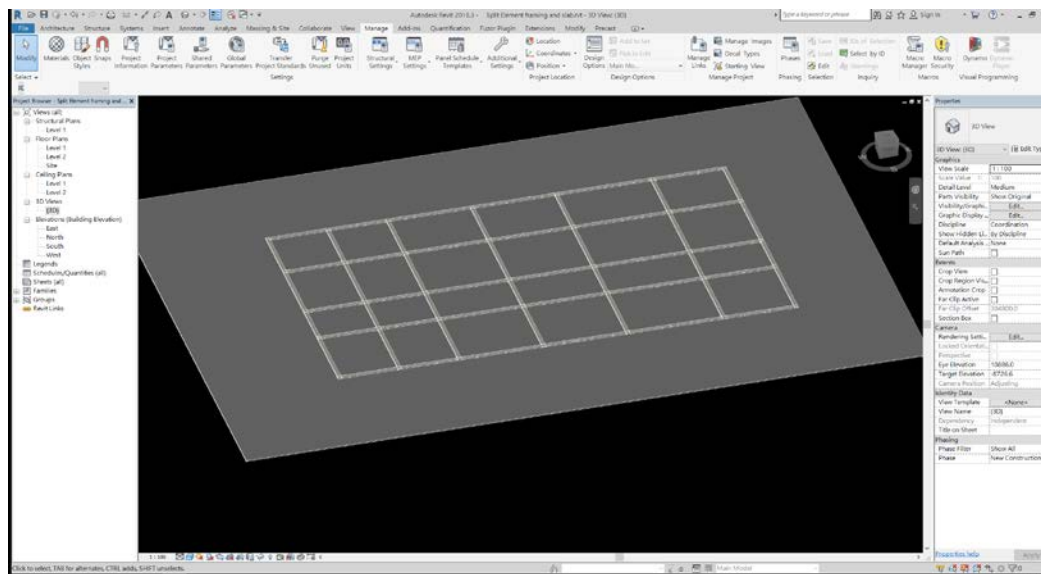

After that, please create one slab and the boundary line should be bigger than the structure framing.
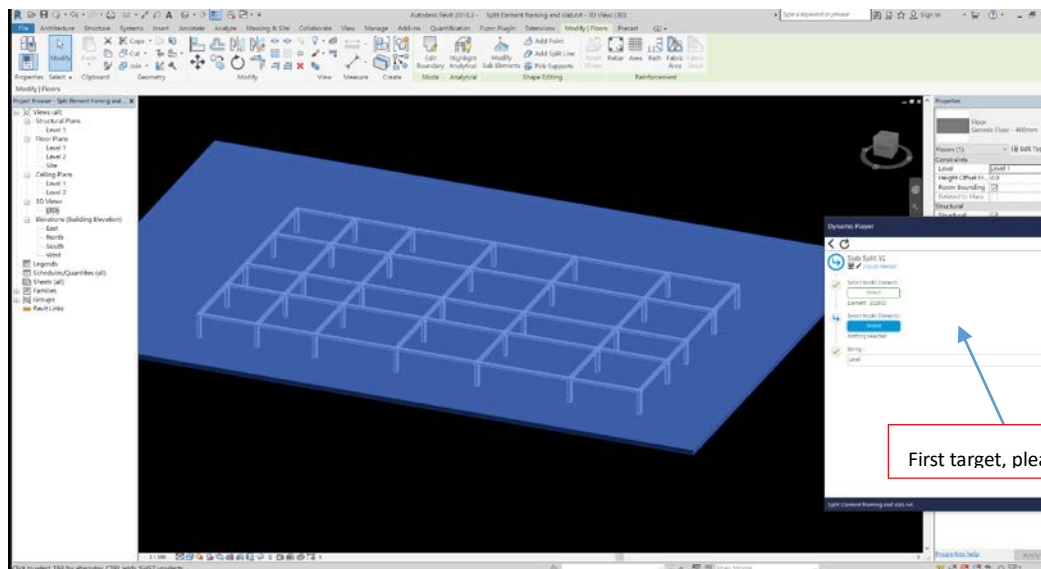

No matter you know or don't know which size you need to select, just create one slab first.
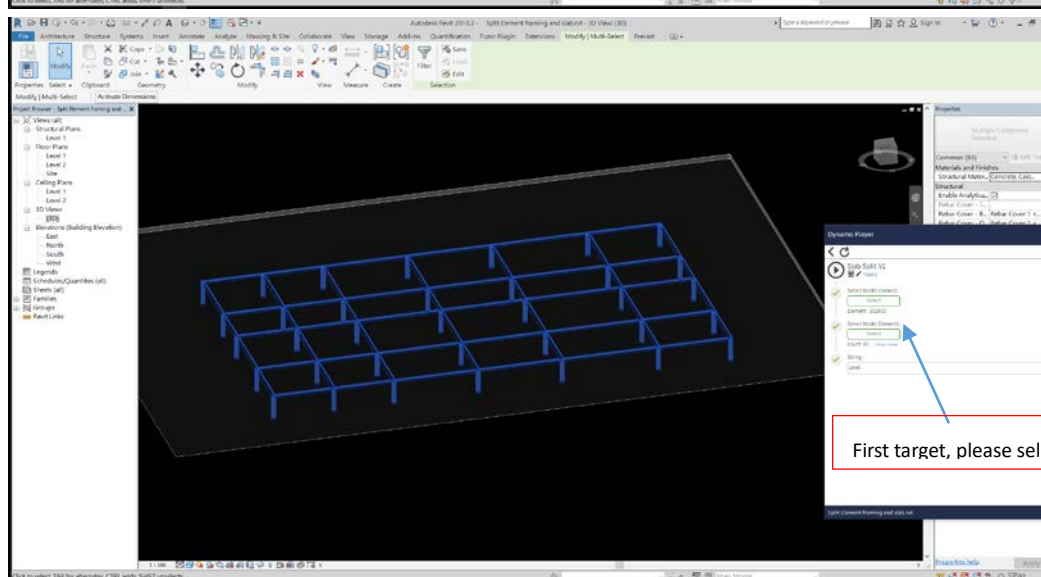

Slab should be intersecting with framing, similar to the following screen capture.

After that use the split slab dynamo.

First target, please select slab

First target, please select Framing

Press Run it and wait. After the process completed, please delete the biggest slab first.

Now you can see the individual slab.
